```

### 2.5 Segment tree

**Description:** A segment tree with range updates and sum queries that supports three types of operations:

- Increase each value in range [1, r] by x (i.e. a[i] += x).
- Set each value in range [l, r] to x (i.e. a[i] = x).
- Determine the sum of values in range [l, r].

$$\sum_{i=1}^{n} i^{6} = \frac{n^{2}(n+1)(2n$$

# 3.3 Pythagorean triple

- A Pythagorean triple is a triple of positive integers a, b, and c such that  $a^2 + b^2 = c^2$ .
- If (a, b, c) is a Pythagorean triple, then so is (ka, kb, kc) for any positive integer k.
- A primitive Pythagorean triple is one in which *a*, *b*, and *c* are coprime.
- Generating Pythagorean triple
  - Euclid's formula: with arbitrary 0 < n < m, then:

$$a = m^2 - n^2$$
,  $b = 2mn$ ,  $c = m^2 + n^2$ 

form a Pythagorean triple.

To obtain primitive Pythagorean triple, this condition must hold: *m* and *n* are coprime, *m* and *n* have opposite parity.

# 4 String

#### 4.1 Prefix function

**Description:** the prefix function of a string s is defined as an array pi of length n, where pi[i] is the length of the longest proper prefix of the sub-string s[0..i] which is also a suffix of this sub-string.

Time: O(|S|).

prefix\_function.h, 15 lines

```
vector<int> prefix_function(const string &s) {
    int n = (int) s.length();
    vector<int> pi(n);
    vector(int) pi(n);
    for (int i = 1; i < n; ++i) {
        int j = pi[i - 1]; // try length pi[i - 1] + 1.
        while (j > 0 && s[j] != s[i]) {
            j = pi[j - 1];
            }
        if (s[j] == s[i]) {
            pi[i] = j + 1;
        }
}
return pi;
```

#### 4.2 Z function

**Description:** for a given string 's', z[i] = longest common prefix of 's' and suffix starting at 'i'. z[0] is generally not well defined (this implementation below assume z[0] = 0).

Time: O(n).

*z\_function.h,* 15 lines

```
vector<int> z_function(const string &s) {
      int n = (int) s.size();
      vector<int> z(n);
      z[0] = 0;
      // [1, r)
      for (int i = 1, l = 0, r = 0; i < n; ++i) {
          if (i < r) z[i] = min(r - i, z[i - l]);
          while (i + z[i] < n \&\& s[z[i]] == s[i + z[i]]) ++z[i];
          if (i + z[i] > r) {
              1 = i;
              r = i + z[i];
12
13
      return z:
14
15 }
```

# 4.3 Counting occurrences of each prefix

**Description:** count the number of occurrences of each prefix in the given string. **Time:** O(n).

counting\_occur\_of\_prefix.h, 18 lines

```
#include "prefix_function.h"
vector<int> count_occurrences(const string &s) {
    vector<int> pi = prefix_function(s);
    int n = (int) s.size();
    vector<int> ans(n + 1);
    for (int i = 0; i < n; ++i) {
        ans[pi[i]]++;
}</pre>
```

Can Tho University Page 11 of 24

```
for (int i = n - 1: i > 0: --i) {
           ans[pi[i - 1]] += ans[i];
11
      for (int i = 0; i <= n; ++i) {
13
           ans[i]++;
14
      return ans;
15
      // Input: ABACABA
17
      // Output: 4 2 2 1 1 1 1
18 }
```

# 4.4 Knuth-Morris-Pratt algorithm

**Description:** searching for a sub-string in a string.

Time: O(N + M).

KMP.h. 14 lines

```
1 #include "prefix_function.h"
vector<int> KMP(const string &text, const string &pattern) {
      int n = (int) text.length();
      int m = (int) pattern.length();
      string s = pattern + '$' + text;
      vector<int> pi = prefix_function(s);
      vector<int> indices;
      for (int i = 0; i < (int) s.length(); ++i) {</pre>
          if (pi[i] == m) {
               indices.push_back(i - 2 * m);
11
12
      return indices;
13
14 }
```

#### Suffix array

Description: suffix array is a sorted array of all the suffixes of a given string. Usage:

- sa[i] = starting index of the i-th smallest suffix.
- rank[i] = rank of the suffix starting at 'i'.
- lcp[i] = longest common prefix between 'sa[i 1]' and 'sa[i]'
- for arbitrary 'u v', let i = rank[u] 1, j = rank[v] 1 (assume i < j), then longest\_common\_prefix(u, v) =  $\min(\text{lcp}[i + 1], \text{lcp}[i + 2], ..., \text{lcp}[j])$

Time:  $O(N \log N)$ .

suffix\_array.h, 42 lines

```
struct SuffixArray {
      string s;
      int n, lim;
      vector<int> sa, lcp, rank;
      SuffixArray(const string &_s, int _{lim} = 256) : s(_s), n(s.length() + 1),
          \lim(_{\lim}, \sin(n), \log(n), \operatorname{rank}(n) 
           s += '$';
           build(); kasai();
           sa.erase(sa.begin()); lcp.erase(lcp.begin());
          rank.pop_back(); s.pop_back();

# 6 Number Theory

#### 6.1 Euler's totient function

- Euler's totient function, also known as **phi-function**  $\phi(n)$  counts the number of integers between 1 and n inclusive, that are **coprime to** n.
- Properties:
  - Divisor sum property:  $\sum_{d|n} \phi(d) = n$ .
  - $\phi(n)$  is a **prime number** when n = 3, 4, 6.
  - If *p* is a prime number, then  $\phi(p) = p 1$ .
  - If *p* is a prime number and  $k \ge 1$ , then  $\phi(p^k) = p^k p^{k-1}$ .
  - If *a* and *b* are **coprime**, then  $\phi(ab) = \phi(a) \cdot \phi(b)$ .
  - In general, for **not coprime** a and b, with d = gcd(a, b) this equation holds:

$$\phi(ab) = \phi(a) \cdot \phi(b) \cdot \frac{a}{\phi(d)}$$

- With  $n = p_1^{k_1} \cdot p_2^{k_2} \cdots p_m^{k_m}$ :

$$\phi(n) = \phi(p_1^{k_1}) \cdot \phi(p_2^{k_2}) \cdots \phi(p_m^{k_m})$$
$$= n \cdot \left(1 - \frac{1}{p_1}\right) \cdot \left(1 - \frac{1}{p_2}\right) \cdots \left(1 - \frac{1}{p_m}\right)$$

- Application in Euler's theorem:
  - If gcd(a, M) = 1, then:

$$a^{\phi(M)} \equiv 1 \pmod{M} \Rightarrow a^n \equiv a^{n \bmod{\phi(M)}} \pmod{M}$$

Can Tho University Page 14 of 24

- In general, for arbitrary a, M and  $n \ge \log_2 M$ :

$$a^n \equiv a^{\phi(M) + [n \bmod \phi(M)]} \pmod{M}$$

Time:  $O(N \log N)$ .

phi\_euler\_totient\_function.h, 14 lines

```
const int MAXN = (int) 2e5;
2 int etf[MAXN + 1];
 void sieve(int n) {
      for (int i = 0; i <= n; ++i) {
          etf[i] = i;
      for (int i = 2; i <= n; ++i) {</pre>
          if (etf[i] == i) {
              for (int j = i; j \le n; j += i) {
                  etf[j] -= etf[j] / i;
```

#### Mobius function

• For a positive integer  $n = p_1^{k_1} \cdot p_2^{k_2} \cdots p_m^{k_m}$ :

$$\mu(n) = \begin{cases} 1, & \text{if } n = 1\\ 0, & \text{if } \exists k_i > 1\\ (-1)^m & \text{otherwise} \end{cases}$$

- Properties:
  - $-\sum_{d|n} \mu(d) = [n=1].$
  - If *a* and *b* are **coprime**, then  $\mu(ab) = \mu(a) \cdot \mu(b)$ .
  - Mobius inversion: let *f* and *g* be arithmetic functions:

$$g(n) = \sum_{d|n} f(d) \Leftrightarrow f(n) = \sum_{d|n} \mu\left(\frac{n}{d}\right)g(d)$$

Time:  $O(N \log N)$ .

mobius\_function.h, 10 lines

```
const int MAXN = (int) 2e5;
2 int mu[MAXN + 1];
 void sieve(int n) {
     mu[1] = 1;
     for (int i = 1; i <= n; ++i) {
          for (int j = 2 * i; j <= n; j += i) {
              mu[j] -= mu[i];
```

# Primes

Approximating the number of primes up to *n*:

n	$\pi(n)$	$\frac{n}{\ln n - 1}$
$100 (1e^2)$	25	28
$500 (5e^2)$	95	96
$1000 (1e^3)$	168	169
$5000 (5e^3)$	669	665
$10000 (1e^4)$	1229	1218
$50000 (5e^4)$	5133	5092
$100000 (1e^5)$	9592	9512
$500000 (5e^5)$	41538	41246
$1000000 (1e^6)$	78498	78030
$5000000 (5e^6)$	348513	346622

 $(\pi(n))$  = the number of primes less than or equal to n,  $\frac{n}{\ln n - 1}$  is used to approximate

#### 6.4 Wilson's theorem

A positive integer n is a prime if and only if:

$$(n-1)! \equiv n-1 \pmod{n}$$

#### Zeckendorf's theorem

The Zeckendorf's theorem states that every positive integer n can be represented uniquely as a sum of one or more distinct non-consecutive Fibonacci numbers. For example: 64 = 55 + 8 + 1

85 = 55 + 21 + 8 + 1

# Bitwise operation

- $a + b = (a \oplus b) + 2(a \& b)$
- $a \mid b = (a \oplus b) + (a \& b)$
- $a \& (b \oplus c) = (a \& b) \oplus (a \& c)$
- $a \mid (b \& c) = (a \mid b) \& (a \mid c)$
- a & (b | c) = (a & b) | (a & c)

- $a \mid (a \& b) = a$
- a & (a | b) = a
- $n = 2^k \Leftrightarrow !(n \& (n-1)) = 1$   $-a = \sim a + 1$
- $4i \oplus (4i + 1) \oplus (4i + 2) \oplus (4i + 3) = 0$

• Iterating over all subsets of a set and iterating over all submasks of a mask:

mask.h, 18 lines

```
1 int n;
void mask_example() {
       for (int mask = 0; mask < (1 << n); ++mask) {
           for (int i = 0; i < n; ++i) {
               if (mask & (1 << i)) {
                   // do something...
           // Time complexity: O(n * 2^n).
10
      for (int mask = 0; mask < (1 << n); ++mask) {
           for (int submask = mask; ; submask = (submask - 1) & mask) {
               // do something...
               if (submask == 0) break;
           // Time complexity: O(3^n).
17
18 }
```

Can Tho University Page 15 of 24

### 6.7 Pollard's rho algorithm

**Description:** Pollard's rho is an efficient algorithm for integer factorization. The algorithm can run smoothly with n upto  $10^{18}$ , but be careful with overflow for larger n (e.g.  $10^{19}$ ).

pollard\_rho.h, 84 lines

41
42
```

#### 6.10 Bitset sieve

**Description:** sieve of eratosthenes for large n (up to  $10^9$ ).

Time: time and space tested on codeforces:

• For  $n = 10^8$ : 200 ms, 6 MB.

• For  $n = 10^9$ : 4000 ms, 60 MB.

bitset\_sieve.h, 23 lines

```
1 const int N = (int) 1e8:
2 bitset<N / 2 + 1> isPrime;
3 void sieve(int n = N) {
      isPrime.flip();
      isPrime[0] = false;

16
17
          array<bool, S> block{};
          for (auto &[p, idx] : cp) {
18
               for (; idx < S + L; idx += p) block[idx - L] = true;</pre>
19
20
21
          for (int i = 0; i < min(S, R - L); ++i) {
22
               if (!block[i]) primes.push_back((L + i) * 2 + 1);
23
24
25
      for (int p : primes) is_prime[p] = true;
26
      return primes;
27 }
```

### 7 Combinatorics

### 7.1 Catalan numbers

$$C_n = \frac{1}{n+1} {2n \choose n} = \frac{(2n)!}{n!(n+1)!}$$

$$C_{n+1} = \sum_{i=0}^{n} C_i C_{n-i}, C_0 = 1, C_n = \frac{4n-2}{n+1} C_{n-1}$$

• The first 12 Catalan numbers (n = 0, 1, 2, ..., 11):

 $C_n = 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786$ 

- Applications of Catalan numbers:
  - difference binary search trees with *n* vertices from 1 to *n*.
  - rooted binary trees with n + 1 leaves (vertices are not numbered).
  - correct bracket sequence of length 2 \* n.
  - permutation [n] with no 3-term increasing subsequence (i.e. doesn't exist i < j < k for which a[i] < a[j] < a[k]).
  - ways a convex polygon of n + 2 sides can split into triangles by connecting vertices.

Can Tho University Page 17 of 24

#### 7.2 Fibonacci numbers

$$F_n = \begin{cases} 0, & \text{if } n = 0\\ 1, & \text{if } n = 1\\ F_{n-1} + F_{n-2}, & \text{otherwise} \end{cases}$$

• The first 20 Fibonacci numbers  $(n = 0, 1, 2, \dots, 19)$ :

 $F_n = 0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181$ 

• Binet's formula:

$$F_n = \frac{\varphi^n - \psi^n}{\varphi - \psi} = \frac{\varphi^n - \psi^n}{\sqrt{5}}$$

where 
$$\varphi = \frac{1 + \sqrt{5}}{2}$$
,  $\psi = \frac{1 - \sqrt{5}}{2}$ 

• Properties:

$$F_{2n+1} = F_n^2 + F_{n+1}^2 F_{2n} = F_{n-1} \cdot F_n + F_n \cdot F_{n+1}$$

$$F_{n+1} \cdot F_{n-1} - F_n^2 = (-1)^n n \mid m \Leftrightarrow F_n \mid F_m \gcd(F_n, F_m) = F_{\gcd(n,m)}$$

# 7.3 Stirling numbers of the first kind

Number of permutations of *n* elements which contain exactly *k* permutation cycles.

$$S(0,0) = 1$$

$$S(n,k) = S(n-1,k-1) + (n-1)S(n-1,k)$$

$$\sum_{k=0}^{n} S(n,k)x^{k} = x(x+1)(x+2)\dots(x+n-1)$$

# 7.4 Stirling numbers of the second kind

Partitions of *n* distinct elements into exactly *k* non-empty groups.

$$S(n,1) = S(n,n) = 1$$

$$S(n,k) = S(n-1,k-1) + kS(n-1,k)$$

$$S(n,k) = \frac{1}{k!} \sum_{i=0}^{k} (-1)^{k-i} {k \choose i} i^n$$

### 7.5 Derangements

Permutation of the elements of a set, such that no element appears in its original position (no fixied point). Recursive formulas:

$$D(n) = (n-1)[D(n-1) + D(n-2)] = nD(n-1) + (-1)^n$$

### 10.6 Eulerian path

#### 10.6.1 Directed graph

**Description:** Hierholzer's algorithm. An Eulerian path in a directed graph is a path that visits all edges exactly once. An Eulerian cycle is a Eulerian path that is a cycle. **Time:** *O*(*E*).

eulerian\_path\_directed.h, 16 lines

```
vector<int> find_path_directed(const vector<vector<int>> &g, int s) {
      int n = (int) g.size();
      vector<int> stack, cur_edge(n), vertices;
      stack.push_back(s);
      while (!stack.empty()) {
          int u = stack.back();
          stack.pop_back();
          while (cur_edge[u] < (int) g[u].size()) {</pre>
              stack.push_back(u);
10
              u = g[u][cur\_edge[u]++];

#### 10.9 2-SAT

Description: finds a way to assign values to boolean variables a, b, c,.. of a 2-SAT problem (each clause has at most two variables) so that the following formula becomes true:  $(a \mid b) & (\neg a \mid c) & (b \mid \neg c) \dots$ Usage:

Can Tho University Page 24 of 24

- TwoSat twosat(number of boolean variables);
- twosat.either(a, ~b): // a is true or b is false
- twosat.solve(); // return true iff the above formula is satisfiable

**Time:** O(V + E) where V is the number of boolean variables and E is the number of clauses.
